New in MDLxL 0.34.0 An AI that looks first

The AI looks first, then changes once

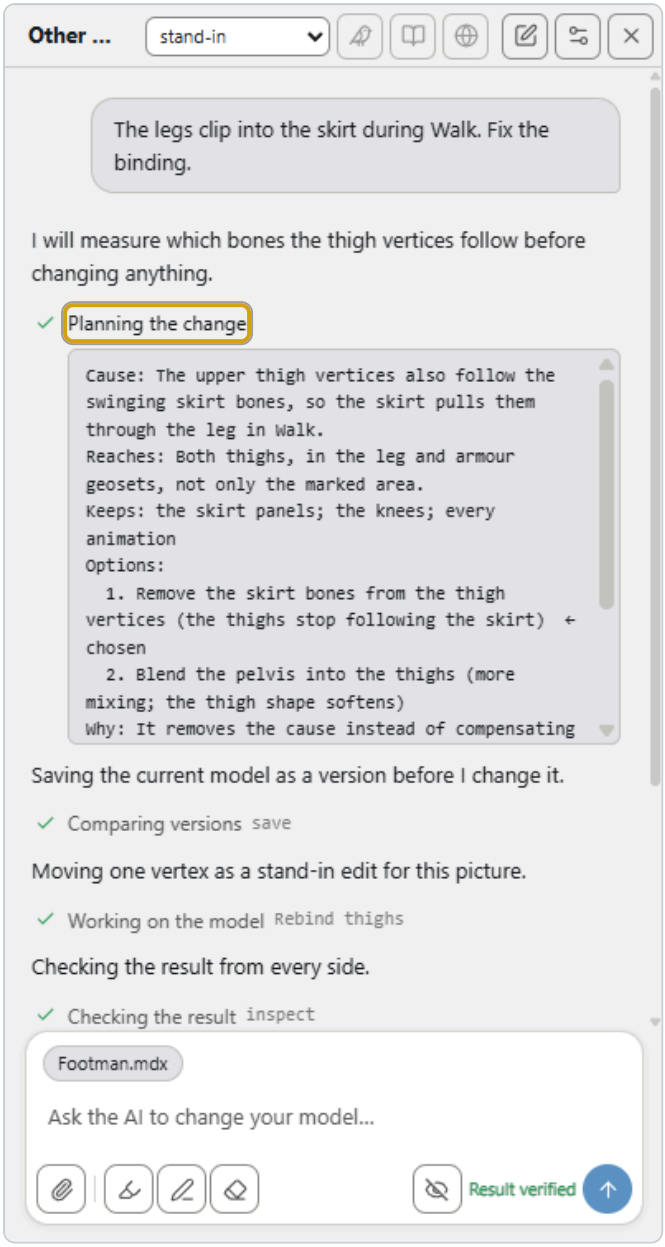

Before its first edit on a job, the AI now writes a short plan. MDLxL refuses its edits until the plan exists. The plan says:

- what is actually wrong, as the AI measured it in the model;
- how far the problem reaches: often more than the area you marked, sometimes less;
- what must stay the same;
- at least two different ways to fix it, what each one costs, and which one it chose and why.

A finished job: the Planning the change step, the edit, the checks and the outside check.

Click the **Planning the change** step to read the plan. Simple edits, such as "set the alpha to 0.5" or a rename, need no plan.

The plan, opened: cause, reach, what to keep, the options and the choice.

Versions side by side

The AI no longer has to patch on top of a bad result. MDLxL keeps versions of the model while the AI works:

- **original**: the model before the first AI edit since you opened it;
- **before job 1**, **before job 2** and so on: the model before each job;
- versions the AI saves itself, for example "repair only".

The AI can compare any two, measure them side by side, and make the model exactly one of them again. Going back is one normal Undo step. Ask it "go back to the version before the last job" and it does. Versions last until MDLxL closes.

Decision diary

For every model, MDLxL keeps a short diary of each AI job: your request, what the AI chose and why, what it changed, how it turned out and what you said next. Every new job reads the latest entries, so earlier AI edits are treated as choices that can be undone, not as part of your model.

- The diary stays when you switch between Codex and Claude, when a helper's memory fills up, and with **Keep a summary** after saving.
- **Wipe it all** after saving deletes it together with the chats.

Outside check

When the AI says an edit is finished, a separate AI that never saw its work judges the result. It only gets your request, what the AI promised to keep, the AI's own measurements and the before/after pictures.

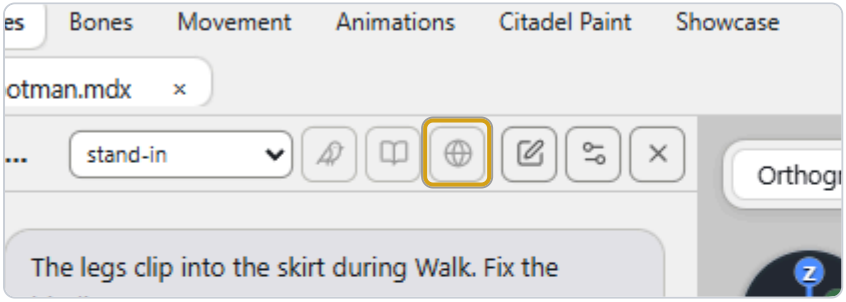

- It answers good, doubtful or wrong, with how sure it is and what it saw.
- A doubtful or wrong answer sends the job back for more work before you see it.
- Each verdict is an **Outside check** step in the chat, with a tick when good and a cross otherwise. Click it to read what it saw.
- It is on by default and costs one extra AI call per finished edit. Turn it off with **Outside check** in **Connection settings**.

Thinking effort and web research

Connection settings: Thinking effort and Outside check.

Thinking effort sets how hard the AI thinks before each step: Provider default, Medium, **High** (the default) or Extra high. Higher is slower and uses more of your plan or credits, but plans and checks edits more carefully.

The globe next to the book is Web research.

The globe switch, **Web research**, lets the AI search the web and read pages such as Hive Workshop tutorials when it needs to look something up. It is off by default and works with Codex, Claude Code and the Claude API. The AI treats what pages say as information only.

> With the **Editing handbook** on, each job now also carries the full guide it needs, for example the binding guide for "the legs clip into the skirt". Patterns from reference models, and rules you pass on in the chat, are treated as evidence to check against your model, not as orders.

Other new features

Glow Up for big weapons

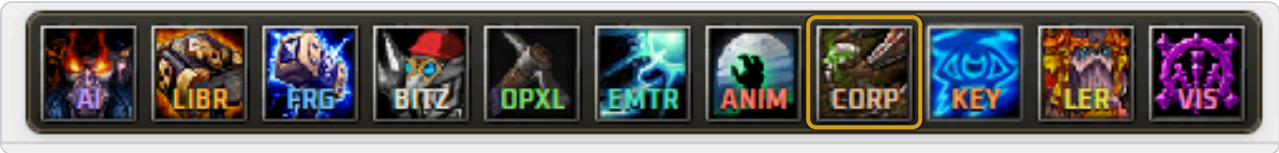

The two weapon-glow ends can be dragged freely, for example onto a hammer or axe head. **Origin brightness %** and **Weapon brightness %** are separate sliders. Dragging a handle pauses the animation, and moving handles are easier to grab.

Auto update offer

The first time a copy of MDLxL starts with Auto update off, it asks once whether to tell you when a new version is out. Nothing is downloaded until you choose **Update and restart**.

CORP label

The **CORP** button's label is now light and easy to read.

The module dock with the CORP button.
